

Quadratic Functions

Functions of the form $f(x) = ax^2 + bx + c$ where a determines the shape of the graph ($a \neq 0$).
 general form

If $a > 0$, it will open **above**, so the vertex is the **minimum point**

a

0

a

0

called the "leading coefficient"

If $a < 0$, it will open **below**, so the vertex is the **maximum point**

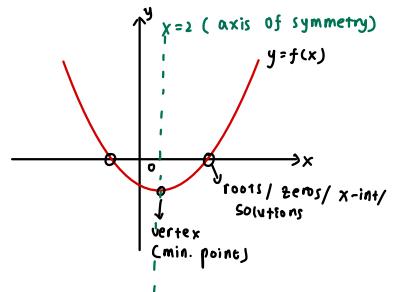

a

0

a

0

Quadratic functions can also be in **vertex form**: $y = a(x-h)^2 + k$ where (h, k) is the coordinate of the **vertex**
root form: $y = a(x-x_1)(x-x_2)$ where x_1 and x_2 are the **zeros/solutions/roots**.

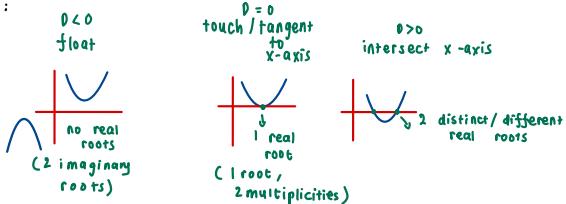

What is **D** (discriminant)? Why is it important?

$D = b^2 - 4ac$ in the quadratic function $y = ax^2 + bx + c$.

It is a number to determine the **characteristics** of quadratic functions.

3 cases of **D**:

Rational and Irrational roots

If $D = b^2 - 4ac$ is a **perfect square** ($D = 1, 4, 9, 16, 25, 36, 49, 64, \dots$)

, then the roots are **rational** and **distinct**.

$$X_1 = \frac{-b}{2a} \quad \text{and} \quad X_2 = \frac{2}{2a} \quad (\text{for example})$$

\rightarrow rational

$2.5 \rightarrow$ rational

$2.321782 \rightarrow$ irrational

$2.331331331 \rightarrow$ rational

If $D = b^2 - 4ac$ is **NOT** a perfect square,

then the roots are **irrational** and **conjugate** of each other.

$$X_1 = 2 + \sqrt{3} \quad \text{and} \quad X_2 = 2 - \sqrt{3} \quad (\text{for example})$$

conjugate

$$X_2 = \frac{-2 + \sqrt{3}}{3}$$

$$X_1 = \frac{-2 - \sqrt{3}}{3}$$

What is the **quadratic formula**?

It is a formula to find the root(s) / x-intercept of a quadratic function and equation.

$$X_{1,2} = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a} = \frac{-b \pm \sqrt{D}}{2a}$$

so,

$$X_1 = \frac{-b + \sqrt{D}}{2a} = \frac{-b + \sqrt{b^2 - 4ac}}{2a} \quad X_2 = \frac{-b - \sqrt{D}}{2a} = \frac{-b - \sqrt{b^2 - 4ac}}{2a}$$

$$X_2 = \frac{-b - \sqrt{D}}{2a} = \frac{-b - \sqrt{b^2 - 4ac}}{2a}$$

no real roots
numbers < real
imaginary

When $D < 0$, the inside of the square root will be negative, e.g., $X_{1,2} = \frac{-b \pm \sqrt{-9}}{3}$, so the roots

will be **imaginary** because negative numbers don't have square roots.

Note: When **factoring quadratics**, the left hand side or the right hand side of the equation must = 0.

$$x^2 + x - 6 = 0$$

find 2 numbers:

- when added = 1

- when multiplied = -6

$$(x+3)(x-2) = 0$$

Factorization Exercises:

1) $6x^2 - x - 5 = 0$

$$x_1 = 1, x_2 = -\frac{5}{6}$$

$$(x-1)(6x+5) = 0$$

8) $10x^2 - 43x + 28 = 0$

$$(5x-4)(2x-7) = 0$$

$$x = \frac{4}{5} \text{ or } x = \frac{7}{2}$$

2) $12x^2 = 25x$

$$12x^2 - 25x = 0$$

$$x(12x - 25) = 0$$

$$x = 0 \quad 12x - 25 = 0$$

$$x = \frac{25}{12}$$

3) $3x^2 + x = 2$

$$x_1 = -1, x_2 = \frac{2}{3}$$

4) $5x^2 = -21x - 18$

$$\underline{6} + \underline{15} = 21$$

$$\underline{6} \times \underline{15} = 90$$

$$x = -3 \text{ or } x = -\frac{6}{5}$$

5) $-10x^2 - 29x - 10 = 0$

$$(2x+5)(5x+2) = 0$$

$$x = -\frac{5}{2} \text{ or } x = -\frac{2}{5}$$

6) $12m^2 + 34m - 56 = 0$

$$2(x+4)(6x-7) = 0$$

$$x = -4 \text{ or } x = \frac{7}{6}$$

7) $x^4 - 2x^3 - 3x^2 = 0$

$$x^2(x^2 - 2x - 3) = 0$$

$$x = -1 \text{ or } x = 3 \text{ or } x = 0$$

8) $2x^3 - 9x + 6 = 0$

$$-4 + -3 = -7$$

$$-4 \times -3 = 12$$

$$\underline{\underline{(2x-4)(2x-3)}}$$

$$\underline{\underline{2(x-2)(2x-3)}}$$

$$= (x-2)(2x-3)$$

How to graph quadratic functions? (Remember! $y = f(x)$)

General form

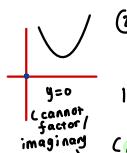

$$y = ax^2 + bx + c$$

$$\text{e.g. } y = 2x^2 + 5x - 1$$

Steps:

- ① $a < 0$ or $a > 0$
(Is the graph opening above or below?)

$$a > 0$$

$$y = 2x^2 + 5x - 1$$

$$2(0) + 5(0)$$

$$y = 0$$

$$(0, 0)$$

- ② x -intercept / roots
 $\rightarrow y = 0$

$$\text{If cannot factor, check } D = b^2 - 4ac$$

$$(discriminant) \quad (-2.6, 0) \text{ and } (0.186, 0)$$

$$0 = 2x^2 + 5x - 1$$

$$x_{12} = \frac{-5 \pm \sqrt{33}}{4}$$

$$x_1 = -2.6$$

$$x_2 = 0.186$$

$$(-2.6, 0) \text{ and } (0.186, 0)$$

- ③ y -intercept $\rightarrow x = 0$
(if exists)

$$y = 2x^2 + 5x - 1$$

$$y = 2(0) + 5(0) - 1$$

$$y = -1$$

$$(0, -1)$$

- ④ Vertex coordinates

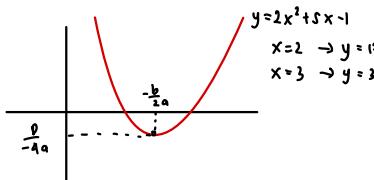

$$x \text{ (axis of symmetry)} = -\frac{b}{2a}$$

$$y \text{ (max or min value)} = \frac{b^2 - 4ac}{-4a} = \frac{D}{-4a}$$

$$-\frac{b}{2a}$$

$$-\frac{D}{-4a}$$

- ⑤ additional points (optional)
(any x values you would like to try)

Vertex form

$$y = a(x-h)^2 + k$$

$$\text{e.g. } y = 2(x-1)^2 + 5$$

Steps:

- ① $a < 0$ or $a > 0$
(Is the graph opening above or below?)

$$a > 0$$

- ② x -intercept / roots
 $\rightarrow y = 0$

$$\text{If cannot factor, check } D = b^2 - 4ac$$

$$(discriminant) \quad (-2.6, 0) \text{ and } (0.186, 0)$$

$$\rightarrow y = 0 \text{ (need to expand)}$$

$$\text{If cannot factor, check } D = b^2 - 4ac$$

$$(use square root method)$$

- ③ y -intercept $\rightarrow x = 0$
(if exists)

$$y = 2x^2 + 5x - 1$$

$$y = 2(0) + 5(0) - 1$$

$$y = -1$$

$$(0, -1)$$

- ④ Vertex coordinates
 $x = h$ and $y = k$
(careful with the signs)

$$x = -\frac{b}{2a}$$

$$y = \frac{b^2 - 4ac}{-4a}$$

$$-\frac{D}{-4a}$$

$$-\frac{b^2 - 4ac}{-4a}$$

$$-\frac{D}{-4a}$$

- ⑤ additional points (optional)
(any x values you would like to try)

Root / Factored form

$$y = a(x-x_1)(x-x_2)$$

$$\text{e.g. } y = -2(x-2)(x-3)$$

Steps:

- ① $a < 0$ or $a > 0$
(Is the graph opening above or below?)

- ② x -intercept / roots
 $x = x_1$ and $x = x_2$

If, for example: $y = (x-1)^2$,
then the x -int is $x=1$ (only one intercept)

- ③ y -intercept $\rightarrow x = 0$
(if exists)

- ④ Vertex coordinates (you'll need to expand the brackets)

$$x \text{ (axis of symmetry)} = -\frac{b}{2a}$$

$$y = \frac{b^2 - 4ac}{-4a}$$

$$-\frac{D}{-4a}$$

- ⑤ additional points (optional)
(any x values you would like to try)

What is the domain and range of a function?

The domain of a function is the x-span of the graph/function, written as D_f .

It is the range of values of x for which $y=f(x)$ is defined.

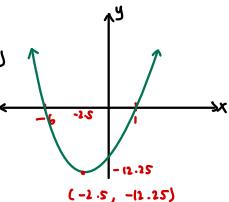

The range of a function is the y-span of the graph/function, written as R_f .

It is the range of values of y for which $y=f(x)$ is defined.
the function

for example, $y=x^2+5x-6$

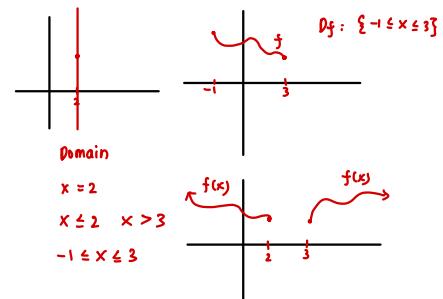

$$= (x+6)(x-1)$$

domain:

as you can see, the x will span/go to the left and to the right endlessly. So, it spans for every x values.

Therefore, $D_f : \{x \in \mathbb{R}\}$ (the domain of x^2+5x-6 is all real numbers.)

range:

as you can see, the vertex is the minimum point with coordinate $(-2.5, -12.25)$. from the graph, the y -value doesn't go down below the vertex. the graph/function only goes up endlessly.

so, y must be greater than -12.25 .

Therefore, $R_f : \{y \geq -12.25, y \in \mathbb{R}\} \rightarrow \text{set } \{y \text{ is a real number}\}$

real numbers < imaginary numbers

(the range of x^2+5x-6 is for $y=f(x)$ greater than -12.25).

* quick way to find R_f (range) from quadratic functions:

Given $y=ax^2+bx+c$, the range depends on a . Is $a < 0$ or $a > 0$?

If $a > 0$ then R_f is $y \geq \frac{D}{-4a}$.

If $a < 0$ then R_f is $y \leq \frac{D}{-4a}$.

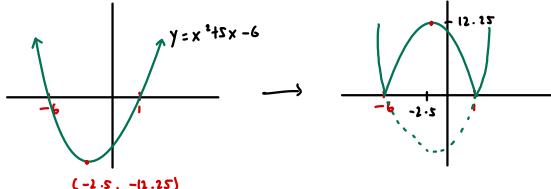

* Using Geogebra (download app or go to geogebra.org/calculator).

* Modulus of quadratic functions

The modulus or absolute of a quadratic function is turning all the negative values of $f(x)$ to positive.

If $f(x)$ is already positive, then the value doesn't change.

for example: $y=x^2+5x-6 \rightarrow y=|x^2+5x-6|$

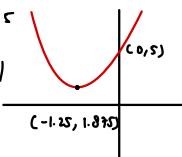

(the graph below the y-axis is reflected or changed the opposite way/upwards. the values above the x-axis don't change).

the vertex coordinates change from $(-2.5, -12.25)$ to $(-2.5, 12.25)$

(the x-coordinate doesn't change)

for graphs like $y=2x^2+5x+5$

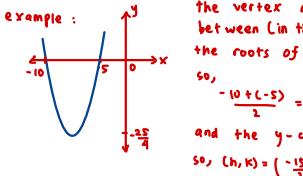

the graph of $y=|2x^2+5x+5|$ doesn't change.

Finding the quadratic function given its graph.

Given vertex and an arbitrary point:

- First, find vertex coordinates (h, k)
- substitute (h, k) to $y = a(x-h)^2 + k$
- find the other arbitrary point on the graph and also substitute it to (x, y) and find the value of a .
- return to the vertex form and substitute (h, k) and the value of a which you found. However, don't substitute the (x, y) .

The vertex always lies between (in the middle of) the roots of a quadratic function.
so,
 $\frac{-10 + (-5)}{2} = \frac{-15}{2} = h$
and the y -coordinate (k) is $-\frac{25}{4}$
so, $(h, k) = \left(-\frac{15}{2}, -\frac{25}{4}\right)$

Substitute to vertex form:

$$\begin{aligned} y &= a(x-h)^2 + k \\ y &= a(x-(-\frac{15}{2}))^2 + (-\frac{25}{4}) \\ y &= a(x+\frac{15}{2})^2 - \frac{25}{4} \end{aligned}$$

Then, substitute another arbitrary point on the graph, for example, $(-2, -3) = (x, y)$

$$\begin{aligned} 0 &= a(-2 - (-\frac{15}{2}))^2 - \frac{25}{4} \\ 0 &= a(\frac{11}{2})^2 \\ a &= 1 \end{aligned}$$

Then, go back to the vertex form without substituting x and y .

$$\begin{aligned} y &= a(x-h)^2 + k \\ y &= 1(x+7.5)^2 - 6.25 \\ y &= (x+7.5)^2 - \frac{25}{4} \end{aligned}$$

Given roots / x -intercepts and an arbitrary point

- find the roots / x -intercepts and label them as x_1 and x_2 , sometimes quadratic functions can have one root with 2 multiplicities, e.g., $y = (x-1)^2$ with $x_1 = 1$.
- use the factored / root form of quadratic function: $y = a(x-x_1)(x-x_2)$ and substitute the x_1 and x_2 there. For two-multiplicity root, substitute to $y = a(x-x_1)^2$
- find the other arbitrary point on the graph and also substitute it to (x, y) and find the value of a .
- return to the factored form and substitute x_1, x_2 , and the value of a which you found. However, don't substitute the (x, y) .

Note: this form can't be used for quadratics which do not have root(s) or float.

Example: using the same graph to the left, we can see that the roots are $x_1 = -10$ and $x_2 = -5$ and $(-\frac{15}{2}, -\frac{25}{4})$ is the arbitrary point (x, y) .

$$\begin{aligned} \text{so, } y &= a(x-x_1)(x-x_2) \\ y &= a(x+10)(x+5) \end{aligned}$$

$$\begin{aligned} \text{Then, } -\frac{25}{4} &= a\left(-\frac{15}{2}+10\right)\left(-\frac{15}{2}+5\right) \\ -\frac{25}{4} &= a\left(\frac{5}{2}\right)\left(-\frac{5}{2}\right) \\ a &= 1 \end{aligned}$$

Then, go back to factored form without substituting x and y .

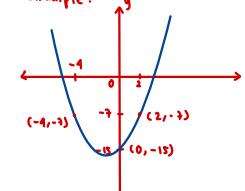

$$y = (x+10)(x+5) = x^2 + 15x + 50.$$

Given 3 arbitrary points:

- find 3 arbitrary points on the graph and label them as $(x_1, y_1), (x_2, y_2)$, and (x_3, y_3) .
- Using the general form of a quadratic function: $y = ax^2 + bx + c$, substitute (x_1, y_1) to make first equation: $y_1 = ax_1^2 + bx_1 + c$.
- do the same for (x_2, y_2) and (x_3, y_3) and gain 3 equations in terms of a, b, c .
- You should obtain a system of 3 equations, try to solve for a, b , and c with the help of substitution and elimination.
- substitute the values of a, b, c you found to $y = ax^2 + bx + c$

Note: this form cannot be used if only 2 points or less are known from the graph.

Example:

There are 3 arbitrary points on the graph, $(-4, -3), (0, -15), (2, -3)$

for first point:

$$\begin{aligned} y &= ax^2 + bx + c \\ -3 &= a(-4)^2 + b(-4) + c \quad \text{Equation 1} \end{aligned}$$

for second point:

$$\begin{aligned} -15 &= a(0)^2 + b(0) + c \\ c &= -15 \quad \text{Equation 2} \end{aligned}$$

for third point:

$$\begin{aligned} -3 &= a(2)^2 + b(2) + c \\ -3 &= 4a + 2b + c \quad \text{Equation 3} \end{aligned}$$

Substituting $c = -15$ to ① and ③

$$\text{to ① : } -3 = 16a - 4b - 15$$

$$16a - 4b = 6$$

$$4a - b = 2 \quad \dots \text{④}$$

$$\text{to ③ : } -3 = 4a + 2b - 15$$

$$4a + 2b = 8 \quad \dots \text{⑤}$$

Solving ④ and ⑤ using elimination gives $a = 1$ and $b = 2$

$$\text{so, } y = x^2 + 2x - 15 //$$

Solving quadratic equations using square root method

When the middle term of a quadratic equation is missing: $y = ax^2 + c$
the equation can be solved

Solving Equations with Square Roots

When the middle term is missing (or cancels), the equation can be solved using square roots. Don't forget \pm when taking the square root of both sides of an equation.

$$\text{Ex 1} \quad 2x^2 - 288 = 0$$

$$\text{Ex 2} \quad \frac{1}{4}x^2 - 3 = 9$$

$$2x^2 = 288$$

$$\frac{1}{4}x^2 = 12$$

$$x^2 = 144$$

$$x^2 = 48$$

$$x = \pm 12$$

$$x = \pm \sqrt{48}$$

$$x = \pm 4\sqrt{3}$$

Equations that look like $a(x-p)^2 + q = 0$ can also be solved with square roots

$$\text{Ex 3} \quad 2(2x+1)^2 - 72 = 0$$

$$2(2x+1)^2 = 72$$

$$(2x+1)^2 = 36$$

$$2x+1 = \pm\sqrt{36}$$

$$2x+1 = \pm 6$$

$$2x+1 = 6 \quad \text{or} \quad 2x+1 = -6$$

$$2x = 5 \quad \text{or} \quad 2x = -7$$

$$x = 2.5 \quad \text{or} \quad x = -3.5$$

TRY – Solve Each Equation

$$\text{a) } x^2 - 9 = 29 \quad \text{b) } 9b^2 = 64 \quad \text{c) } 25x^2 - 10 = 71 \quad \text{d) } 3n^2 - 6 = 78 \quad \text{e) } -3(x+1)^2 + 27 = 0$$

$$7. (4x^{-3}y^5)^2 = \frac{16y^{10}}{x^6}$$

$$8. \frac{(2a^2b)^{-3}}{(ab^2)^{-4}} = \frac{(ab^2)^4}{(2a^2b)^3} = \frac{a^4b^8}{8a^6b^3} = \frac{b^5}{8a^2}$$

$$9. (36x^{-4})^{-\frac{1}{2}} = \frac{x^2}{6}$$

$$10. \frac{(64p^2q^{-2/3})^{-1/2}}{(p^5q^{10})^{-1/5}} = \frac{(p^5q^{10})^{1/5}}{(8p^2q^{-2/3})^{1/2}} = \frac{8q^2}{8p^2q^{-1/3}} = \frac{q^{2+\frac{1}{3}}}{p} = \frac{q^{\frac{7}{3}}}{p}$$

$$y = 18990$$

Exercise 4

1. Simplify

$$\begin{aligned} \text{a)} & 4g^{x-1} \cdot 7^{2x-3} \\ & = (7^2)^{x-1} \cdot 7^{2x-3} \\ & = 7^{2x-2} \cdot 7^{2x-3} \\ & = 7^{4x-5} \end{aligned}$$

$$\begin{aligned} \text{b)} & 2^{16x} \div (1296^{3x-4} \cdot 36^{x+5}) \\ & = 6^{3x} \div ((6^4)^{3x-4} \cdot (6^2)^{x+5}) \\ & = \frac{6^{3x}}{6^{20x-16} \cdot 6^{2x+10}} = \frac{6^{3x}}{6^{22x-6}} = \frac{6^{3x-22x+6}}{6^{-19x+6}} \end{aligned}$$

$$\text{c)} 64^{3x} \cdot 128^{x-1} \div (32^{2x+3} \div 8^{4x-1})$$

$$\begin{aligned} \frac{(2^6)^{3x} \cdot (2^7)^{x-1}}{\left(\frac{(2^3)^{2x+3}}{(2^3)^{4x-1}}\right)} &= \frac{2^{18x} \cdot 2^{7x-7}}{2^{10x+15}} = \frac{2^{25x-7}}{2^{-2x+18}} = 2^{25x-7+2x-18} \\ &= 2^{27x-25} \end{aligned}$$

4. Solve for x

$$\text{a)} \left(\frac{4}{3}\right)^{5x} = \left(\frac{64}{343}\right)^{2x-1} \quad x=3$$

$$\begin{aligned} \text{b)} \left(\frac{125}{216}\right)^{-\frac{x}{2}} &= \left(\frac{6}{5}\right)^{3x+2} \quad \frac{3x}{2} = 3x+2 \\ \left(\frac{216}{125}\right)^{\frac{x}{2}} &= \left(\frac{6}{5}\right)^{3x+2} \quad 3x = 6x+4 \\ \left(\frac{6}{5}\right)^{\frac{x}{2}} &= \left(\frac{6}{5}\right)^{3x+2} \quad -4 = 3x \\ \left(\frac{6}{5}\right)^{\frac{3x}{2}} &= \left(\frac{6}{5}\right)^{3x+2} \quad x = -\frac{4}{3} \end{aligned}$$

$$\begin{aligned} \text{c)} 49\left(\frac{3}{11}\right)^{2x} &= 144 \quad \left(\frac{3}{11}\right)^{2x} = \left(\frac{3}{11}\right)^{-2} \\ \left(\frac{3}{11}\right)^{2x} &= \frac{144}{49} \quad 2x = -2 \\ \left(\frac{3}{11}\right)^{2x} &= \frac{11^2}{7^2} \quad x = -1 \\ \left(\frac{3}{11}\right)^{2x} &= \left(\frac{11}{7}\right)^2 \end{aligned}$$

$$\text{d)} \left(\frac{9}{4}\right)^{x+3} = \left(\frac{9}{27}\right)^{-5} \quad x = \frac{9}{2}$$

$$\begin{aligned} \text{e)} 2^{x-1} &= 128^x \cdot 2^x \\ 2^{x-1} &= 2^{7x} \cdot 2^x \end{aligned}$$

$$\text{f)} 2(6^x)^2 - 74 \cdot 6^x + 72 = 0$$

Hint: write as quadratic equation
with 6^x as the variable

$$2(6^x)^2 - 74 \cdot 6^x + 72 = 0$$

let $a = 6^x$

$$\begin{aligned} 2a^2 - 74a + 72 &= 0 \quad a = 36 \quad \text{or} \quad a = 1 \\ a^2 - 37a + 36 &= 0 \quad 6^x = 36 \quad 6^x = 1 \\ (a-36)(a-1) &= 0 \quad 6^x = 6^2 \quad 6^x = 6^0 \\ &\quad x = 2 \quad x = 0 \end{aligned}$$

2. Solve for x

$$\text{a)} x^{\frac{1}{2}} = 5$$

$$(x^{\frac{1}{2}})^2 = 5^2 \rightarrow x = 25$$

$$\text{b)} x^{-\frac{1}{2}} = 5$$

$$(x^{-\frac{1}{2}})^{-2} = 5^{-2}$$

$$x = \frac{1}{25}$$

$$\text{c)} x^{\frac{1}{3}} = -5$$

$$(x^{\frac{1}{3}})^3 = (-5)^3$$

$$x = -125$$

$$\text{d)} 4x^{-\frac{3}{2}} = 16$$

$$x^{-\frac{3}{2}} = 4$$

$$(x^{-\frac{3}{2}})^{\frac{2}{3}} = 4^{-\frac{2}{3}}$$

$$x = \frac{1}{4^{\frac{2}{3}}} = \frac{1}{(2^2)^{\frac{1}{3}}} = \frac{1}{8}$$

3. Solve for x:

$$\text{a)} 2^x = 16\sqrt{2}$$

$$2^x = 2^4 \cdot 2^{\frac{1}{2}}$$

$$2^x = 2^{\frac{9}{2}}$$

$$x = \frac{9}{2}$$

$$\text{b)} 2^{-x} = 64 \quad x = -6$$

$$\text{c)} 9^{3x+1} = 27^{3x} \quad x = \frac{1}{3}$$

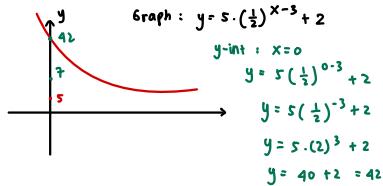

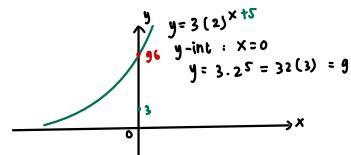

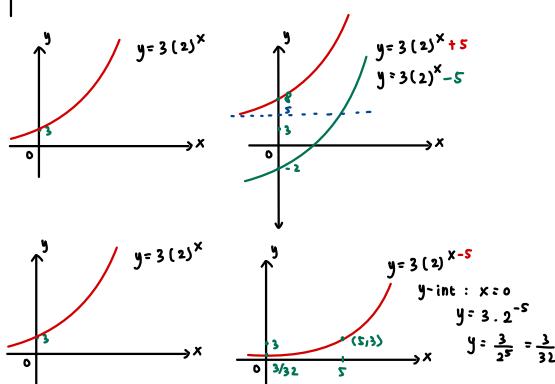

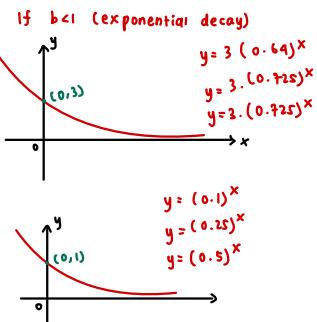

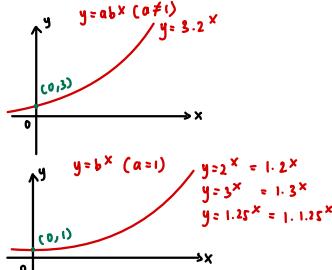

Transforming Exponential Functions ($y = ab^{x \pm h} + k$)

The exponential function $y = ab^{x \pm h} \pm k$ is a combination of transformation of standard exponential function $y = b^x$.

$$y = b^x \xrightarrow{\text{multiply the graph by a factor } a} y = ab^x \xrightarrow{\text{shift the graph to the left if } x+h \text{ or right if } x-h \text{ by } h \text{ units}} y = ab^{x \pm h} \xrightarrow{\text{shift the graph: up if } k \text{ or down if } -k \text{ by } k \text{ units}} y = ab^{x \pm h} \pm k$$

General Form: $y = ab^x$

If $b > 1$ exponential growth

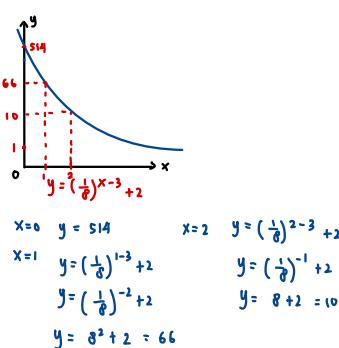

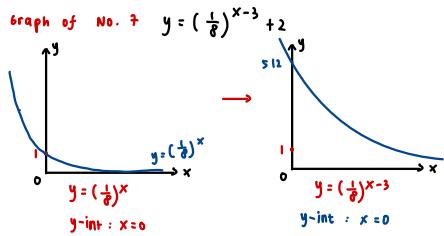

Finding Domain, Range, and Horizontal Asymptote of Graph

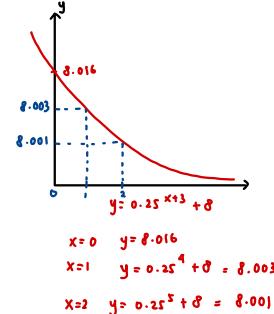

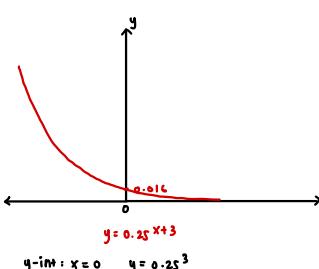

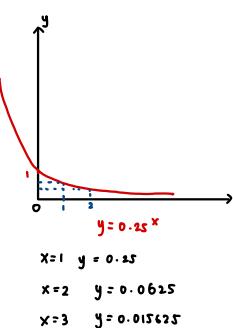

- * The domain (D_f) of $y = ab^x$ is $x \in \mathbb{R}$ (all real numbers)
- range (R_f) of $y = ab^x$ is $y > 0$ with horizontal asymptote $y = 0$
- * The range (R_f) of $y = ab^x + k$ is $y > k$ with horizontal asymptote $y = k$
- $y = ab^x - k$ is $y > -k$ with horizontal asymptote $y = -k$
- * The range of $y = ab^{x \pm h}$ is just $y > 0$ with horizontal asymptote $y = 0$

Exercise: Find the range and the horizontal asymptote:

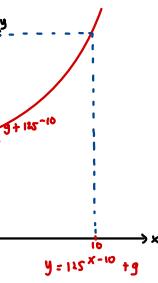

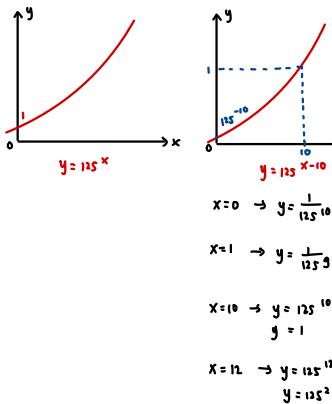

- 1) $y = 2^x$ Rf: $y > 0$ Df: $x \in \mathbb{R}$; horizontal asymptote: $y = 0$
- 2) $y = 2^{x+1}$ Rf: $y > 0$ horizontal asymptote: $y = 0$
- 3) $y = 2^{x-1}$ Rf: $y > 0$ horizontal asymptote: $y = 0$
- 4) $y = 2^x + 2$ Rf: $y > 2$ horizontal asymptote: $y = 2$
- 5) $y = 2^x - 2$ Rf: $y > -2$ h.a.: $y = 2$
- 6) $y = 3^x$ Rf: $y > 0$ h.a.: $y = 0$
- 7) $y = (\frac{1}{8})^{x-3} + 2$ Rf: $y > 2$ h.a.: $y = 2$
- 8) $y = 0.25^{x+3} + 8$ Rf: $y > 8$ h.a.: $y = 8$
- 9) $y = 125^{x-10} + 9$ Rf: $y > 9$ h.a.: $y = 9$
- 10) $y = 2 \cdot 5^x - 3$ Rf: $y > -3$ h.a.: $y = -3$

8) $y = 0.25^{x+3} + \delta$

9) $y = 125^{x-10} + g$

$x=10 \rightarrow y = 125^{10-10} = 1$

$y = g + 1 = 10$

$y = g + 1 = 10$

Exponential Word Problems (Simple and Compound Interest)

(Exponential Growth and Decay)

(Solve for an unknown - initial, final amount and interest rate for compound interest problems - for different computing periods (months, annually, weekly, daily))
